USPTO Provisional Patent Application Cover Sheet (SB/16)

Title of Invention:	Nose-Mounted Tactile Meditation Device
First Named Inventor:	Michael Christopher Usowski
Residence (City & State):	San Anselmo CA 94960
Mailing Address:	17 Parkside Court
Correspondence Address (Email/Phone):	_____
Attorney/Agent (if applicable):	N/A (filing pro se) Provisional
Application Type:	Patent Application
Number of Drawing Sheets:	1
Number of Pages (including drawings):	5
Entity Status:	■ Micro Entity ☐ Small Entity ☐ Large Entity

Provisional Patent Application Draft

Field of the Invention

This invention relates to the field of mindfulness, meditation, and psychotherapeutic tools, and more specifically to tactile devices that enhance breath awareness, concentration, and interoceptive presence by amplifying the felt experience of air moving across the skin. The device engages sensory neurons in the highly innervated area surrounding the nostrils and philtrum, supporting deeper embodiment and anchoring attention through consistent, clearly perceptible physical feedback.

Abstract

The device mounts to the sides of the nostrils, with a main body positioned beneath them, to provide somatosensory engagement without obstructing airflow. By directing attention to the physical sensation of breathing, the device supports concentration, interoceptive awareness, and practices such as meditation, breathwork, and emotional regulation. Serving as a grounding anchor for breath awareness, the device assists users in maintaining present-moment focus and embodied calm, and may be particularly beneficial for individuals experiencing attentional drift, cognitive distraction, or emotional turbulence.

Background of the Invention

Existing meditation and mindfulness tools primarily rely on visual or auditory cues—such as timers, bells, apps, or guided audio—to help users maintain focus. Some wearable devices offer haptic feedback or sensor-based data collection but are often complex, tech-dependent, or limited in their ability to foster embodied presence. These tools may also divert attention outward rather than inward. There remains a clear gap in tools that offer direct, physical engagement with the breath at its most intimate and accessible point—the nostrils and upper lip (philtrum). Despite this area's high neural sensitivity and deep interoceptive potential, few if any meditation aids have been designed to amplify the tactile perception of airflow itself. This invention addresses that gap with a body-mounted device that delivers consistent tactile feedback precisely where breath is felt. In one embodiment, the device requires no external inputs or digital systems, offering a grounded, intuitive aid for attentional focus, somatic regulation, and meditative absorption. The result is a neurologically informed support tool that is portable, accessible, and of potential psychotherapeutic value.

Summary of the Invention

The present invention is a nose-mounted tactile device configured to amplify physical awareness of the breath at its point of entry. In one form, the device includes a formable inner structure, such as a flexible metal wire or mesh, surrounded by a soft, skin-safe exterior material such as silicone, rubber, or foam. In another form, the device is manufactured as a molded soft body that retains its shape without

internal reinforcement. In both cases, the device is shaped as a mirrored pair of S-curves that extend beneath and alongside the nostrils and continue upward along the sides of the nose. This configuration provides light tactile contact and a consistent cue during inhalation and exhalation. The device may be hand-molded or pre-formed to accommodate different nose shapes and sizes, and is designed to be comfortable, lightweight, and portable. Primary applications include meditation, breathwork, somatic regulation, trauma recovery, and daily calming practices. In certain embodiments, the device may also incorporate sensors, vibratory elements, or microelectronics to provide biofeedback, breath pacing guidance, or connectivity with external applications or data systems.

Alternate Embodiments

In addition to the primary forms described above, the invention may be adapted with variations in structure and functionality. In some embodiments, the device may be manufactured without an internal mesh or wire structure. In such cases, the device relies on the molding process and the inherent resilience of the chosen material (e.g., silicone, rubber, or foam) to conform to and remain in place on the nose.

The invention may also incorporate integrated or modular electronic components for enhanced functionality. These embodiments may include:
- Breath sensing elements such as airflow, temperature, or humidity sensors to detect inhale/exhale patterns.
- Micro-vibration modules to provide rhythmic cues or haptic pacing feedback.
- LED indicators or low-light visual cues embedded in the device for subtle breath reminders.
- Wireless communication modules (e.g., Bluetooth) for syncing with meditation apps or journaling platforms.
- Biometric feedback integration, such as heart rate variability (HRV) monitoring or stress indicators.

These features may be embedded directly into the device or added as removable modular attachments. All such versions remain within the spirit and scope of the invention: supporting breath awareness, attentional stability, and embodied presence through tactile engagement with the nose.

Claims

1. A nose-mounted tactile meditation device comprising:
(a) a body shaped as a mirrored pair of S-curves configured to extend beneath and alongside the nostrils and continue upward along the sides of the nose; and
(b) a skin-safe exterior material configured to provide tactile feedback at the point of breath entry during inhalation and exhalation.

2. The device of claim 1, wherein the body further comprises a formable inner structure selected from the group consisting of a flexible metal wire, mesh, or combination thereof, enclosed within the exterior material.

3. The device of claim 1, wherein the body is formed without an internal support structure and is manufactured as a molded soft body that retains its shape and conforms to the nose by resilience of the material.

Brief Description of Drawings

Fig. 1 shows the device in front view, including the main body (10) beneath the nostrils and curved arm sections (12) extending upward.

Fig. 2 shows the device in side view, illustrating the main body (10), nasal engagement section (14), and flexible wire frame (16).

Fig. 3 shows the device in three-quarter side view. The main body (10) rests beneath the nostrils, while the curved arm sections (12) extend upward along the outside of the nostrils. The nasal engagement section (14) provides stable positioning beneath the nose. The device includes a flexible wire frame (16) that allows shaping to individual anatomy, which is encased in a soft material (18) for comfort and skin safety. Optional features may include a textured surface (20) along the main body to enhance tactile feedback, a sensor module (22) embedded within or near the arms for monitoring breath or providing haptic guidance, and modular ends (24) that can be removed or exchanged for cleaning or for diffusion of essential oils. The overall ergonomic curve (26) of the device is designed to conform to the user's nasal structure and provide both comfort and functionality during meditation practice.

Fig 1: Front View

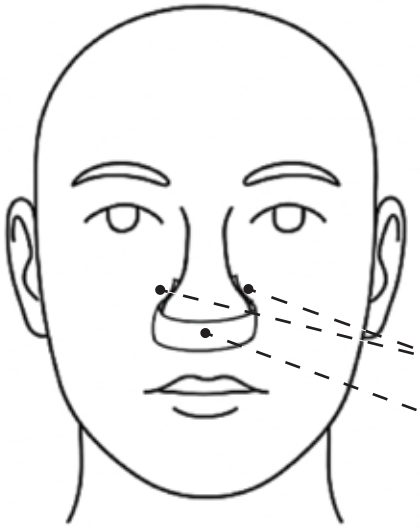

Fig 2: Side View

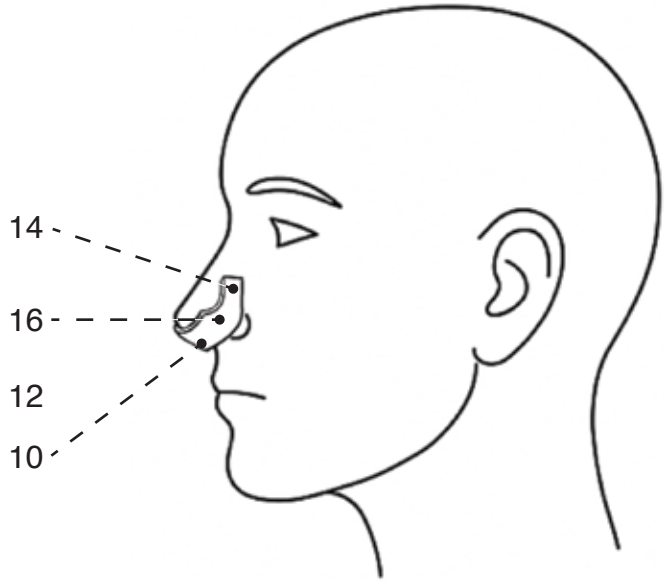

Fig 3: Three-Quarter Side View

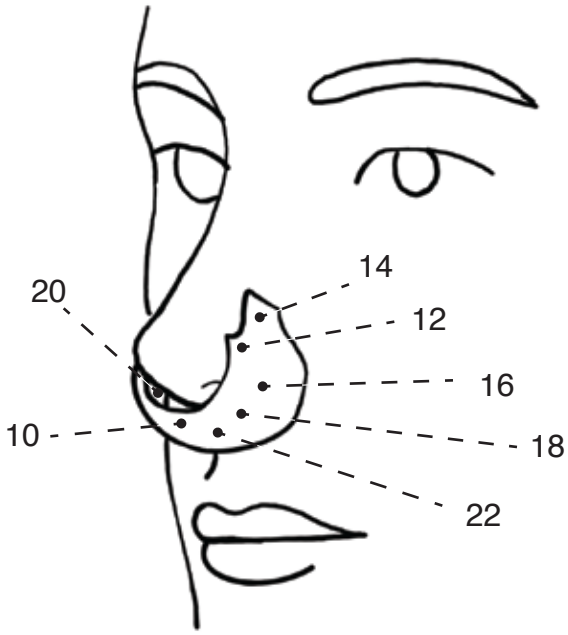

Figure 1-3 Legend and Labels

Main Body (10)
Portion that sits directly beneath the nostrils.

Curved Arm Sections (12)
“S-shaped” or curved arms that hug the nostrils and/or bridge of the nose.

Nasal Engagement Section (14)
The part that makes contact with or stabilizes under/around the nostrils.

Flexible Wire Frame (16)
The bendable frame or shaping element inside with an internal Wire / Mesh Core

Soft Encasing (18)
Silicone or other soft material that encases the wire frame.

Textured / Surface (20)
Raised ridges, soft pads, or textured tips for amplifying sensation and sensory feedback.

Optional Sensor Module (22)
If included, the location of embedded sensors (for breath, HR, vibration, etc.).

Ergonomic Curve (24)
S-shaped contour or ergonomic curvature.
